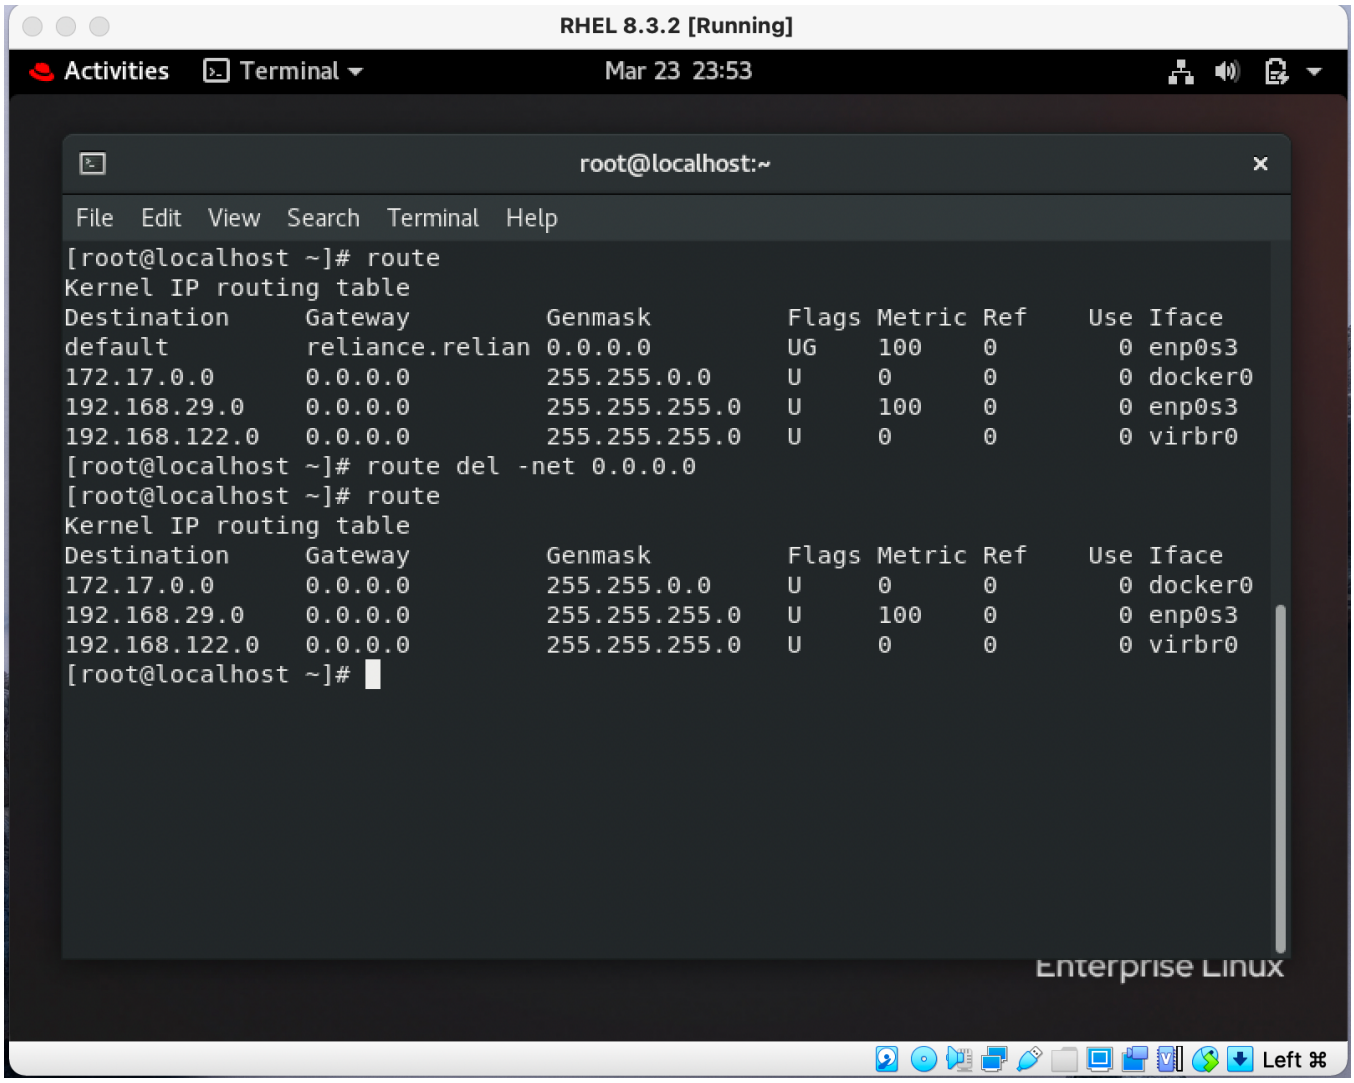
🔰 “Crete a setup so that you can ping google bout not able to ping Facebook from same system”🔰

Ping is a basic Internet program that allows a user to verify that a particular IP address exists and can accept requests.

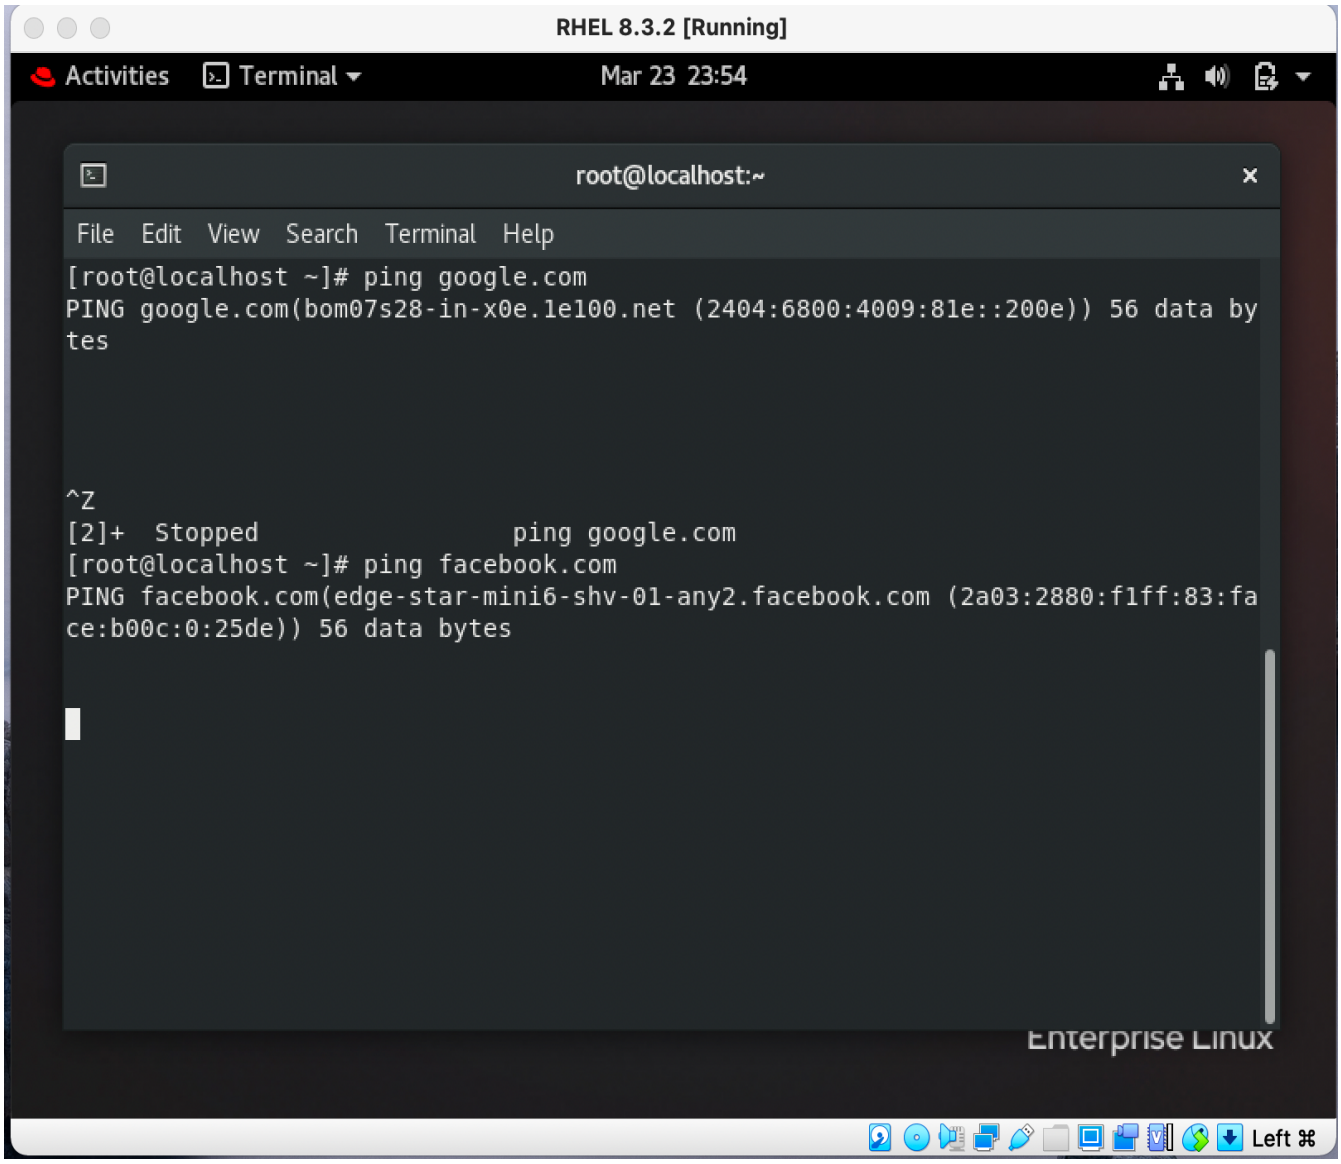
Ping is used diagnostically to ensure that a host computer the user is trying to reach is actually operating.

For this purpose iam using redhat linux

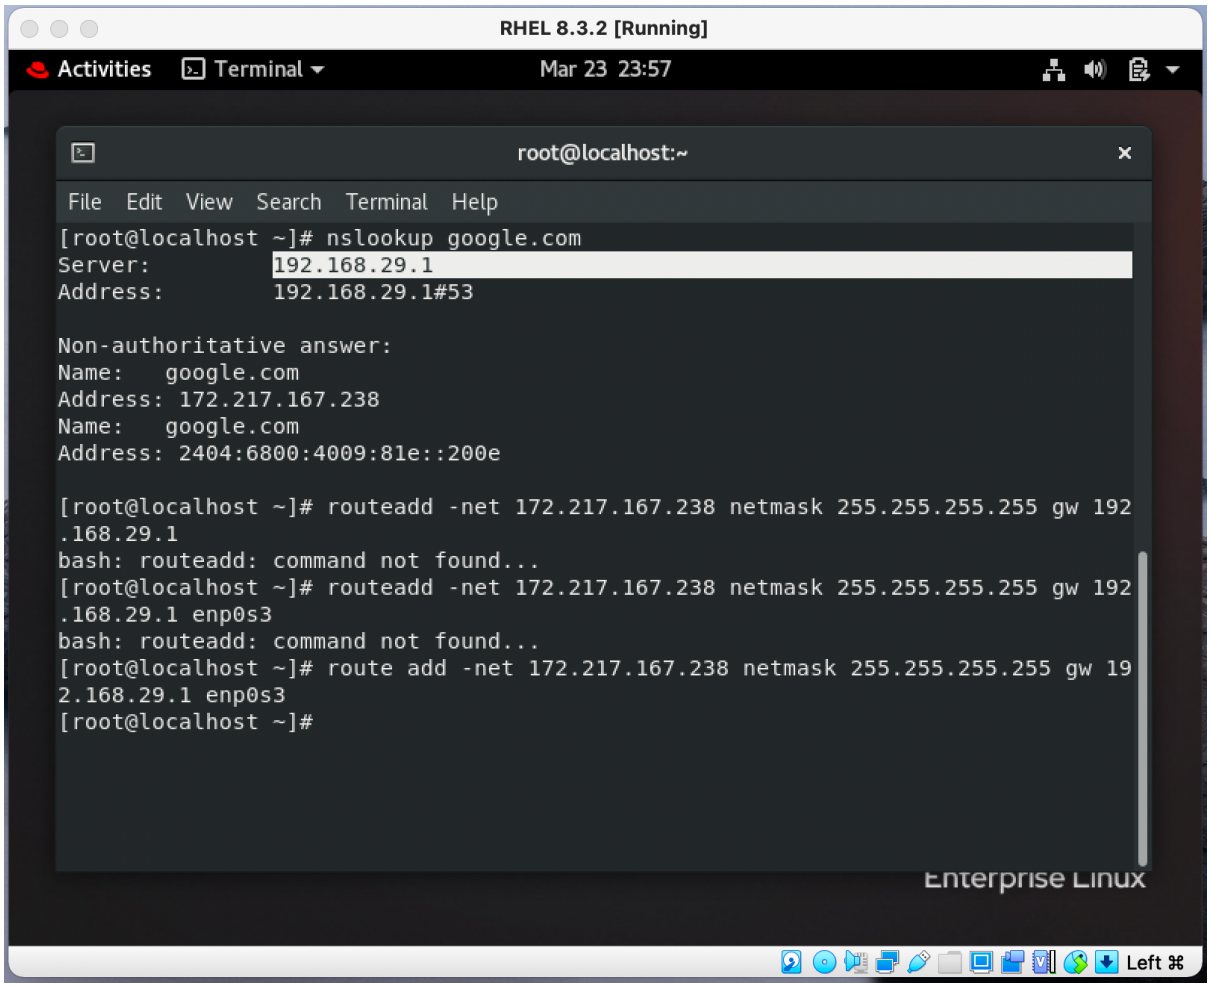
1. First checking the route tables and the gateways



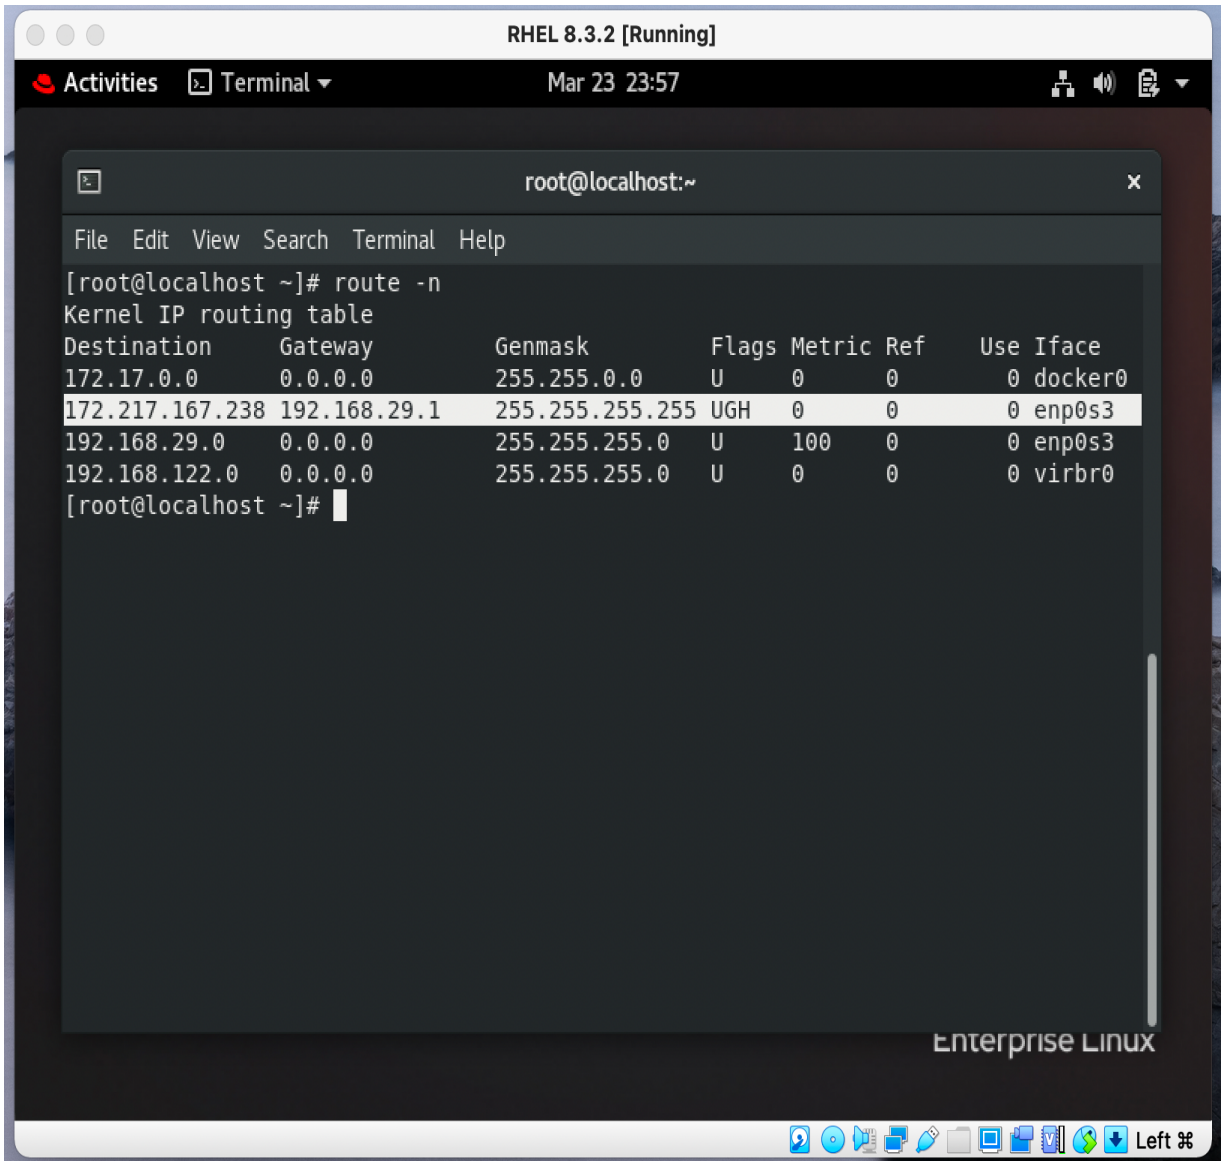
2.Trying to ping google and Facebook but not able to ping because I had deleted the universal route 0.0.0.0



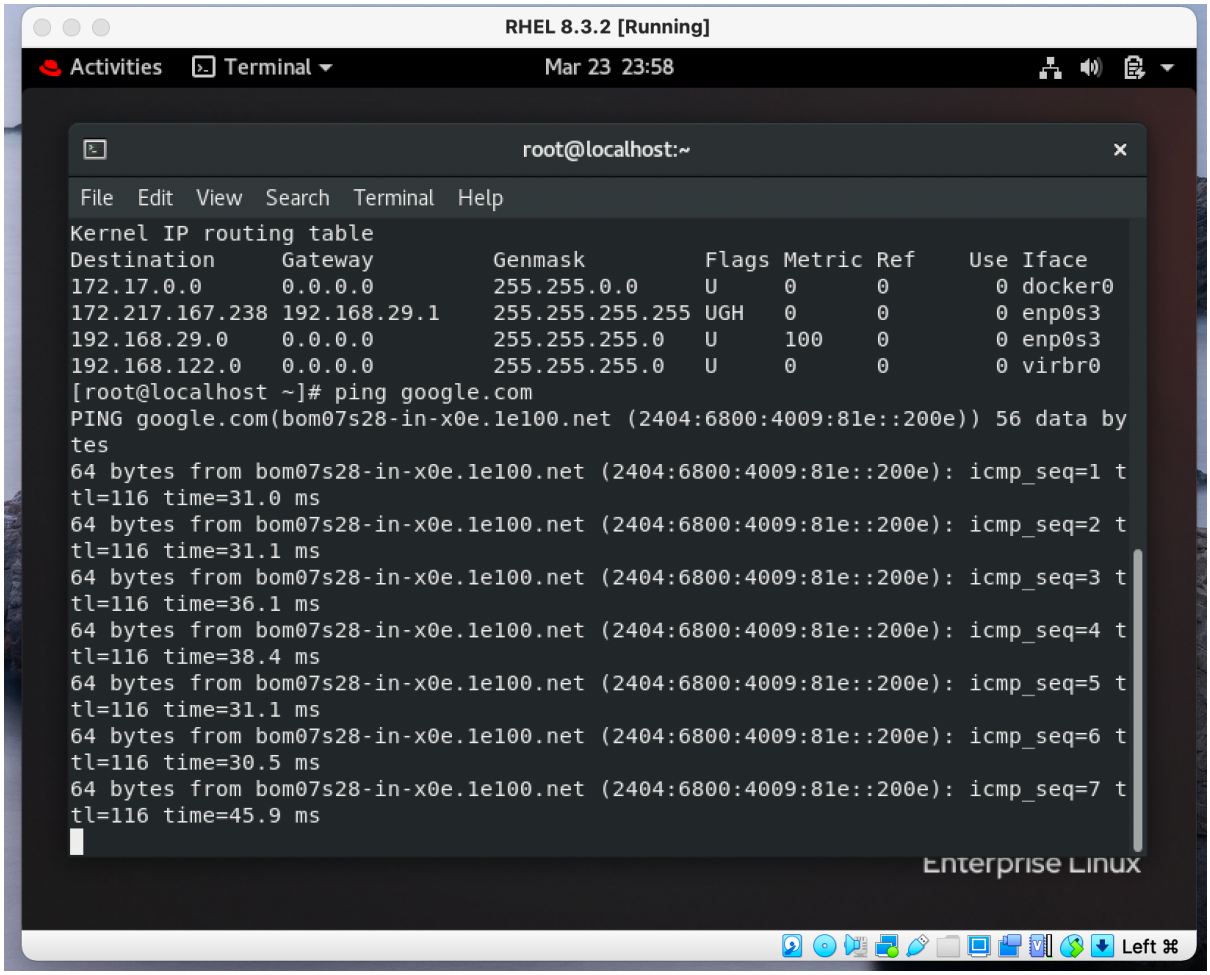
3.Trying to check the ip of Google.com by nslookup. And adding the route to google.com

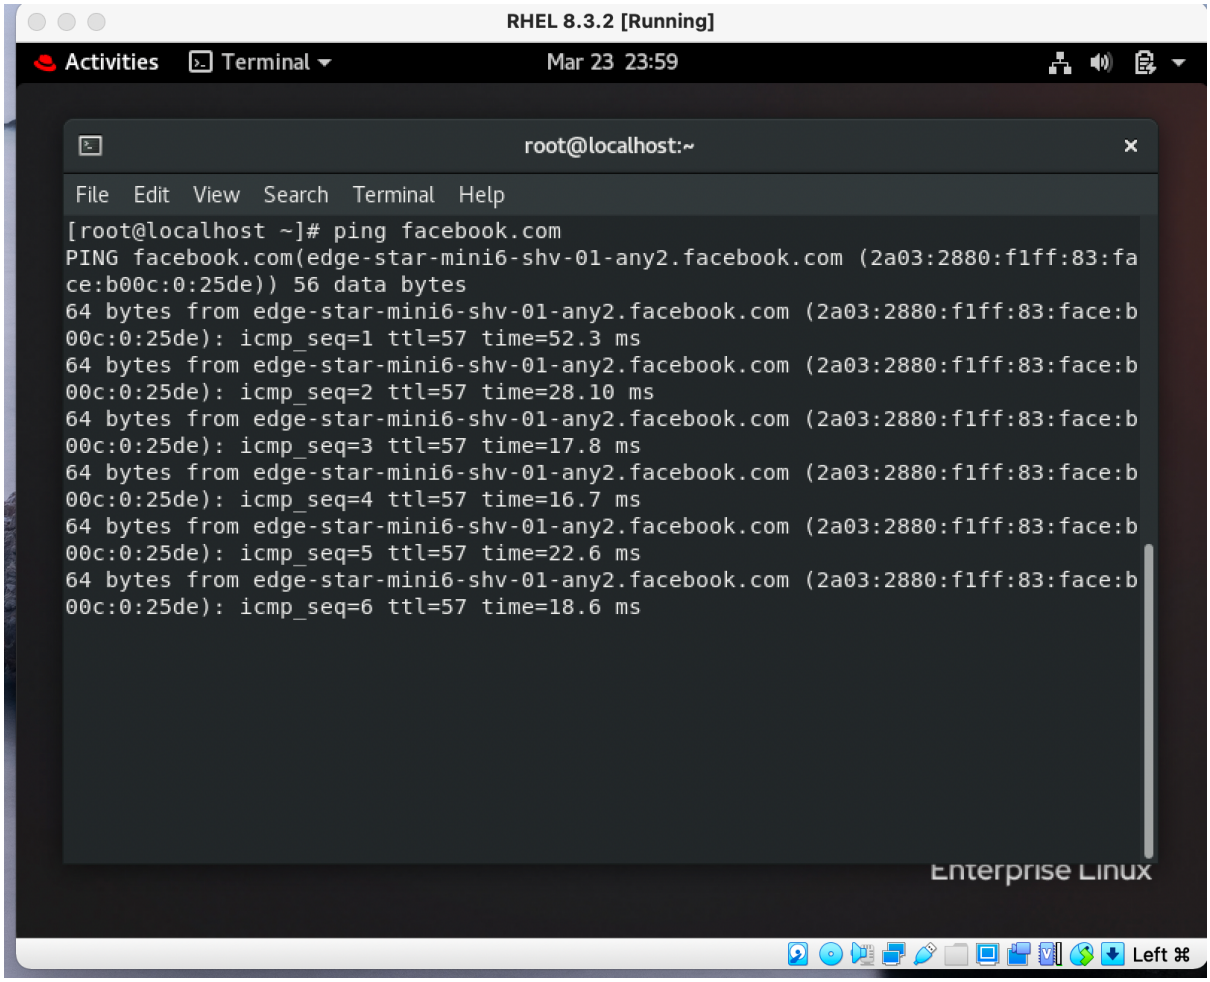


4.The route which I had created is added.



5.Now iam able to ping pinging google.com successfully.





6.Now we cannot ping Facebook because we had added route only for google.com
